Molecular Test for Fragile X Mental Retardation Syndrome

The UNC Hospitals Molecular Genetics Laboratory offers testing of the FMR1 gene responsible for Fragile X syndrome of mental retardation. The specific defect is an expansion of CGG trinucleotide repeats leading to inactivation of the gene.

**Biology of the Disease:** Fragile X Syndrome (FraX) is the most common form of inherited mental retardation with an incidence of approximately 1 in 3600 males and 1 in 4000-6000 females. It is characterized by varying degrees of mental retardation, dysmorphic facial features, behavioral disturbances, developmental delay, autism, and macroorchidism in males. Females tend to be less severely affected. The FMR1 gene is localized to the long arm of the X chromosome (Xq27.3). A variable number of trinucleotide repeats, (CGG)n, is located 5’ of the FMR1 coding sequence, and the number of these CGG repeats is increased in carriers of FraX and even more so in those affected with the disorder. While normal individuals have 5 to about 44 CGG repeats, carriers of the FMR1 “premutation” have about 59-200 repeats, and affected persons with the “full mutation” have more than 200 repeats. Expansion of the CGG sequence to greater than 200 repeats causes aberrant methylation of the CpG sites within the repeat as well as CpG sites within the FMR1 promoter. This results in transcriptional silencing of FMR1 and manifestations of FraX. Women whose genotype lies in the grey zone from 45 to 58 repeats are unlikely to have a child affected by FraX although variable repeat numbers and disease-causing expansions have sometimes been observed among family members.

**Clinical Indications for Testing:** Candidates for testing include individuals with unexplained mental retardation, developmental delay, autism, post-pubertal macroorchidism in males, a family history of fragile X syndrome, or the fetus of a carrier mother. Genetic counseling is recommended.

**Laboratory Testing for the Fragile X mutation:** The preferred sample is ACD or EDTA anticoagulated blood (pale yellow top or lavender top, 7ml) which may be refrigerated up to 48 hours prior to testing. Triplet-primed PCR using gene specific primers that flank the FMR1 CGG repeat region and a (CGG)₅ primer that anneals within the CGG repeat region are used to amplify CGG repeats of all sizes. The resulting PCR products are analyzed and sized by capillary gel electrophoresis. Methylation status for premutations greater than 100 CGG repeats, and full mutations (>200 CGG repeats) is determined by a FMR1 mPCR assay.
